Abstract: The article considers results of a study on determining optimal areas for laser ignition of an oxygen–hydrogen fuel mixture in a model combustion chamber by focusing laser radiation to initiate an optical breakdown spark in a selected zone. The results of numerical simulation of the nonstationary process of mixing the gaseous components — oxygen and hydrogen — are presented with the determination of the parameters of the resulting mixture in the volume of the model combustion chamber carried out in the LOGOS-Prepost software package. Three zones that are most preferable for laser ignition in the chamber are selected among the zones in which focusing of radiation is possible during laser ignition. These zones are located in the regions of flow recirculation exhibiting fuel mixture compositions close to stoichiometric and low flow velocities. Preferential use of the zones for laser ignition selected by the results of the numerical simulation was confirmed by test fires.

Keywords: numerical simulation; combustion chamber; oxygen; hydrogen; laser ignition; optical breakdown
