Abstract: The possibilities of increasing the shock wave energy of an underwater explosion by introducing the explosive with a positive oxygen balance into the composition of the energetic material are analyzed. For the calculations, relatively new compounds were chosen as explosive oxidizers: 3,6-dinitro-1,4-bis(trinitromethyl)-1,4-dihydropyrazolo[4,3-c]pyrazole; 4,4',5,5'-tetranitro-2,2'-bis(trinitromethyl)-2H,2'H-3,3'-bipyrazole; and 2-dinitromethyl-5-nitrotetrazole. The function of explosive fuel was performed by the well-known powerful substances HMX and CL-20. The calculations have shown that compositions containing these explosive oxidizers should have high values of the TNT equivalent in terms of shock wave energy and the most noticeable increase in the TNT equivalent due to the use of these explosive oxidizers should be expected in the case of aluminized compositions.

Keywords: TNT equivalent; explosive; oxygen balance; heat of explosion; aluminum
